GROWTH OF GROUPS DEFINED BY AUTOMATA

ASHLEY S. DOUGHERTY, LYDIA R. KINDELIN, AARON M. REAVES, ANDREW J. WALKER, 
AND NATHANIEL F. ZAKAHI

Abstract. Nekrashevych conjectured that iterated monodromy groups of quadratic polynomials with a pre-periodic kneading sequence have intermediate growth. In this paper we prove intermediate growth for two such groups. We also provide a new proof of intermediate growth for a class of groups containing the Grigorchuk group, previously known to have intermediate growth.

1. Introduction

Finitely generated groups of infinite order grow at many different rates. Growth functions are more commonly polynomial or exponential but there are also cases of intermediate growth. Intermediate growth is more rare, therefore finding groups with this property can lead to a better understanding of the characteristics of these groups. Grigorchuk found the first group of intermediate growth in the 1980’s and they have been studied ever since.

Grigorchuk’s group is generated by an automaton and these mathematical structures are very convenient for finding groups of intermediate growth. Nekrashevych provides a process in his monograph Self Similar Groups for producing an automaton from any given post-critically finite polynomial. He also conjectured that a specific kind of post-critically finite polynomial would produce an automaton which would generate a group of intermediate growth. We have considered this conjecture and found two more groups of intermediate growth using Nekrashevych’s procedure.

The automata produced by Nekrashevych’s process are of a very specific form and the Grigorchuk group does not come from such an automaton. We also looked at automata with similar properties to that of the Grigorchuk group and give a new proof that a known class of automata will produce groups of intermediate growth.

In order to prove intermediate growth of groups we modeled our arguments on those from the paper paper On the Growth of Iterated Monodromy Groups Bux and Pérez [2] with the use of a weight system to represent the length of words. This method can be used to prove intermediate growth for both, groups produced by polynomials in Nekrashevych’s process, and groups generated by any automaton. In this paper we also discuss some of the obstacles we encountered with this method for proving intermediate growth.
2. Background

2.1. Growth.

Definition 2.1. For a finite generating set \( \Sigma \) of a group \( G \) and a map \( \tilde{\ell} : \Sigma \to \mathbb{R}^+ \), the \textit{ball} of radius \( n \), \( B_G(n) \) is the set of all elements \( g \in G \) represented by a word \( w = x_1^{\epsilon_1} x_2^{\epsilon_2} \cdots x_m^{\epsilon_m} \), \( x_i \in \Sigma \), \( \epsilon_i = \pm 1 \), with \( \sum_{i=1}^{n} \tilde{\ell}(i) \leq n \).

Definition 2.2. The \textit{growth function} \( g(n) : \mathbb{N} \to \mathbb{N} \) of \( G \) is defined by \( g(n) = |B_G(n)| \).

Definition 2.3. Let \( f, g \in \mathbb{N} \cup \{0\} \to \mathbb{N} \cup \{0\} \). We say that \( f \preceq g \) if there are constants \( A, B, C \in \mathbb{N} \) such that \( f(n) \leq Ag(Bn) + C \), for all \( n \in \mathbb{N} \cup \{0\} \).

Definition 2.4. Let \( G \) be a group with the finite generating set \( S \) and growth function \( g(n) \). We say \( G \) has polynomial growth if there exists some polynomial \( p(n) \) such that \( g(n) \preceq p(n) \). We say \( G \) has exponential growth if there exists some \( a > 1 \) such that \( a^n \preceq g(n) \). A group \( G \) has intermediate growth if \( p(n) \preceq g(n) \preceq a^n \) for all polynomials \( p \) and some \( a > 1 \). Growth is not dependent on the generating set but is a property of the group in general.

2.2. Automata.

2.2.1. Defining Automata. Except for the definition of the infinite rooted \( n \)-ary tree, the following definitions come from Nekrashevych[1]. The tree definition is general knowledge; our definition comes from Terpstra[3].

Definition 2.5. For an integer \( n \geq 2 \) define \( T^n \) to be the \textit{infinite rooted} \( n \)-\textit{ary tree}. The vertices of \( T^n \) are finite sequences of elements (or possibly \( \emptyset \)) from \( \{0, 1, \ldots, n-1\} \), and the edges of \( T^n \) connect pairs of vertices whose sequences differ in length by 1, and in which the shorter sequence can be obtained by erasing the last term of the longer sequence. For example, vertices \( v_i = (011) \) and \( v_j = (0110) \) would be connected by an edge, while \( v_l = (010) \) and \( v_j = (0110) \) would not. The empty sequence defines the root vertex denoted by \( \emptyset \).

Definition 2.6. Let \( \Gamma \) be a simple graph. An \textit{automorphism} of \( \Gamma \) is a bijection of the vertices that preserves the adjacency and non-adjacency.

Definition 2.7. An \textit{alphabet} is a set \( X \). The \textit{free monoid} on \( X \), denoted \( X^* \), is the set (possibly empty) of all \( n \)-tuples.

Definition 2.8. An \textit{automaton} \( A \) over the alphabet \( X \) is given by

(1) a \textit{set of the states}, usually also denoted by \( A \)
(2) a map \( \tau : A \times X \to X \times A \)

Definition 2.9. It is convenient to define automata using their \textit{Moore diagrams}. A Moore diagram is a directed labeled graph with the vertices identified with the states of the automaton. If \( \tau(q \cdot x) = y \cdot p \), then we write \( q \cdot x = y \cdot p \), and we have an arrow starting in \( q \), ending in \( p \) and labeled by \( (x, y) \). So, the arrows show the state transitions, and their labels show the input and the output.
2.2.2. Groups Generated by Automata. The group generated by the automaton A is the group \( \langle A \rangle \) generated by the transformations defined on all the states of A.

For example, consider the automaton A over the alphabet X containing state q. Then q is represented by an n-tuple where the first coordinate represents how the state acts with 0, the second coordinate is how the state acts with 1, and so on through \( n - 1 \) actions. So, if \( q \cdot 0 = 0 \cdot p \) and \( q \cdot 1 = 1 \cdot r \), then \( q = (p, r) \). This bracket notation means that when the state q acts on the n-ary tree, it does nothing to the 0 but produces a p at the next vertex of the tree and does nothing to 1 but produces an r at the next vertex. This notation is also an easier way to multiply elements of the group. If \( q = (p, r) \) and \( p = (1, q) \) then \( qp = (p, r)(1, q) = (p, rq) \). Another important aspect of the bracket notation is the ease in representing certain automorphisms of the tree. Consider an automorphism \( \alpha := (\alpha_L, \alpha_R) \in \text{Aut}(T^{(2)}) \) where \( \alpha \) preserves each of the two subtrees and acts in \( T^{(2)}_L \) as \( \alpha_L \) and in \( T^{(2)}_R \) as \( \alpha_R \). Now, consider \( \tau \in \text{Aut}(T^{(2)}) \), called the swap, that interchanges \( T^{(2)}_L \) and \( T^{(2)}_R \). So, \( \tau(\alpha_L, \alpha_R) = (\alpha_R, \alpha_L)\tau \). For \( \tau \in \text{Aut}(T^{(3)}) \), \( \tau(\alpha_L, \alpha_C, \alpha_R) = (\alpha_R, \alpha_L, \alpha_C) \).

2.2.3. Nekrashevych’s Process for Creating Groups from Polynomials.

Definition 2.10. An active state \( a \) of an automaton A is a state such that \( a \times x \rightarrow y \times a \) for some \( x \neq y \in X \). Because of this, a state in an automaton may be seen as a string transformation on strings of the alphabet, with an active state \( a \) transforming \( x \) to \( y \) and a non-active state as the identity transformation.

Definition 2.11. For an automaton A with only a single active state and a single arrow leading to and from each non-active state that does not go to the identity state, the kneading sequence of A is the sequence of \( x_i \in X \) labeling the arrows not leading to the identity state. The first arrow, with corresponding \( x_1 \) is the arrow entering the active state, and each successive arrow is the arrow entering the state the previous arrow began at. A periodic kneading sequence is when the kneading sequence is a loop connecting all the labels of the arrows of the Moore diagram. A pre-periodic kneading sequence is when the kneading sequence has a straight path for at least one action and then is a loop connecting the rest of the labels.

Definition 2.12. Let \( p : \mathbb{C} \rightarrow \mathbb{C} \) be a complex polynomial such that \( p(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0 \). A critical point of the polynomial is a solution of \( p'(z) = 0 \). A post-critical point is a point \( p(p(p(\cdots (c)))) \) where \( c \) is a critical point. We say that \( p \) is post-critically finite if the set \( P \) of all post-critical points is finite.

In Nekrashevych’s monograph, Self-Similar Groups, he provides a process for constructing automata from post-critically finite polynomials. These automata can be used to define iterated monodromy groups. We only describe the process for finding these groups, but a thorough discussion of them can be found in the monograph [1]. It is important to note that for any post-critically finite polynomial \( f : \mathbb{R}^2 \rightarrow \mathbb{R}^2 \), if there exists an \( f \)-invariant spider as defined below, there will always exist an automaton which generates the action of \( \text{IMG}(f) \).

Conjecture 2.13. Nekrashevych conjectured that every second degree post-critically finite polynomial with a pre-periodic kneading sequence produces an iterated monodromy group of
intermediate growth.

**Definition 2.14.** A spider $S$ is a collection of disjoint simple curves in the complex plane connecting each of the post-critical points to infinity (since the number of post-critical points is finite, a spider will always exist). For each $z \in P$, we call the curve connecting $z$ to infinity $\gamma_z$. Each curve $\gamma_z$ may not pass through any post-critical points other than its initial point at $z$. A spider $S$ is said to be $f$-invariant if $f(S)$ is isotopic to a subset of $S$ through spiders.

**Definition 2.15.** For a critical point $z \in C$ of local degree $d_z$ of $f$, the set $X_z = f^{-1}(\gamma_{f(z)})$ consists of $d_z$ curves connecting $z$ to infinity. The collection $\{X_z | z \in C\}$ of such sets of curves is called the critical portrait associated to the spider $S$ and the topological polynomial. The curves of the critical portrait will divide the plane into components, called sectors.

For a polynomial $f$ with a finite post-critical set and corresponding $f$-invariant spider $S$, there will exist some critical portrait, $C$. Then let $\{S_x | x \in X\}$ be the set of corresponding sectors, where $X$, with $|X| = d$, is the set of labels of the sectors.

We shall construct the automaton $K_{C,f}$ using $X$ as our alphabet. We label this automaton $K_{C,f}$, as it encodes both the critical portrait $C$ and the action of the polynomial $f$. The procedure is as follows:

**Part A** Take an arbitrary post-critical point $z \in P$. For each $y \in f^{-1}(z)$, if $y$ is not critical, proceed to Part B. Otherwise, skip to Part C.

**Part B** As $y$ is not critical, the local degree of $f$ around $y$ should be 1, and $y$ should be an internal point of a sector $S_x$. This information will be encoded by the output and transition functions of $K_{C,f}$:

$$g_z \cdot x = x \cdot g_y,$$

where $g_y = id$ if $y \notin P$.

**Part C** Since $y$ is critical, it will be on the boundaries of $d'$ sectors. Let these sectors be $S_{x_1}, S_{x_2}, S_{x_3}, \ldots, S_{x_d'}$, listed in counterclockwise order around $y$. The set $X$, which we already defined as the set of labels of the sectors, will then be the set $\{x_1, x_2, x_3, \ldots, x_{d'}\}$. If $y$ is not post-critical, go to Part C-I. If it is post-critical, go to part C-II.

**Part C-I** Since $y$ is not post critical, we encode the action of a small loop around $y$ by setting:

$$g_z \cdot x_i = x_{i+1(mod \ d')} \cdot id$$

for $i = 1, \ldots, d'$.

**Part C-II** Since $y$ is post-critical, there is a path $\gamma_y$ in the spider $S$. We may assume the sectors are labeled in such a way that the curve $\gamma_y$ is adjacent to $S_{x_1}$ and $S_{x_{d'}}$. Let us then encode this by

$$g_z \cdot x_i = x_{i+1} \cdot id$$

for $i = 1, \ldots, d' - 1$ and

$$g_z \cdot x_{d'} = x_1 \cdot g_y.$$
Once this process has been completed for every post-critical point in the set $P$, we can draw the corresponding Moore diagram.

3. Computations of Iterated Monodromy Groups of Polynomials

In this section, we compute the iterated monodromy groups for the polynomials $z^2 - 2$, $z^3 + 3z$, $z^3 - 3z$, and $z^3 + \frac{3}{2}z$. We then show they are all of polynomial growth in Proposition 3.1.

3.1. The Iterated Monodromy Group of $p(z) = z^2 - 2$.

Here, we use a simple example to demonstrate Nekrashevych’s procedure for producing iterated monodromy groups. Consider the polynomial $z^2 - 2$. The derivative of $z^2 - 2$ is $2z$, and when set equal to zero, $z$ must equal zero. Therefore, the set of critical points, $C$, only contains 0. When we substitute 0 into $z^2 - 2$ for $z$, we get $-2$. When $-2$ is similarly substituted back into the polynomial, we get 2, and 2 will always produce another 2 when substituted for $z$. Therefore, the set of post-critical points is $P = \{-2, 2\}$ and $z^2 - 2$ is post-critically finite. Now we will construct the spider $S$. Let

$$\gamma_{-2} = \{ z \in \mathbb{C} \mid z = -2 + it, t \in \mathbb{R}^+ \cup \{0\} \},$$

$$\gamma_{2} = \{ z \in \mathbb{C} \mid z = 2 - it, t \in \mathbb{R}^+ \cup \{0\}\}$$

portrayed in the picture below where

$$f(\gamma_{-2}) = \{ z \in \mathbb{C} \mid (2 - t^2 - 4it), t \in \mathbb{R}^+ \cup \{0\}\},$$

$$f(\gamma_{2}) = \{ z \in \mathbb{C} \mid (2 - t^2 - 4it), t \in \mathbb{R}^+ \cup \{0\}\}.$$
To obtain the line $X_0$ and complete the critical portrait, we set $X_0 = f^{-1}(\gamma_{f(0)})$. Then, $f^{-1}(\gamma_{f(0)}) = f^{-1}(\gamma_{-2}) = \{ z \in \mathbb{C} \mid f(z) = -2 + it, t \in \mathbb{R}^+ \cup \{0\} \}$. Thus:

\[
\begin{align*}
  z^2 - 2 &= -2 + it \\
  z^2 &= it \\
  z^2 &= te^{\frac{2i}{2}} \\
  te^{\frac{2i}{2}} &= r^2 e^{2\theta i} \\
  r^2 &= t \\
  2\theta &= \frac{\pi}{2} + 2\pi n, n \in \mathbb{Z} \\
  \theta &= \frac{\pi}{4} + \pi n
\end{align*}
\]

The last step in labeling the critical portrait is to determine which sector is $S_0$ and which is $S_1$. We want to label the sectors starting with $S_0$ and moving counterclockwise around $X_0$ to label $S_1$. Since we only have two sectors, one valid labeling of the graph is as follows:

Let the post-critical points $-2$ and $2$ be represented by $a$ and $b$ respectively. This gives our set of states $A = \{a, b, id\}$ and our alphabet $X = \{0, 1\}$.

Now let $z$ be the post-critical point $-2$. Then $y = f^{-1}(z) = 0$. Note $0$ is not a post-critical point, but since it is a critical point, it lies on $X_0$. Thus, we set $a \cdot 0 = 1 \cdot id$ and $a \cdot 1 = 0 \cdot id$ as defined by $g_z \cdot x_i = x_{i+1(\text{mod} \ d')} \cdot 1$ for $i = 1, \ldots, d'$ where $S_{x_{d'+1}} = S_{x_1}$. Consider next the other post-critical point $2$. Then $f^{-1}(z) = \{ -2, 2 \}$. Thus, we must finish the procedure for both $y = 2$ and $y = -2$. For $y = 2$, since $2$ is not a critical point and lies in $S_1$, we obtain $b \cdot 1 = 1 \cdot b$ by applying $g_z \cdot x = x \cdot g_y$ where $g_y = 1$ if $y \notin P$. For $y = -2$, we apply the same formula, with the exception that $-2$ lies in $S_0$. This gives $b \cdot 0 = 0 \cdot a$. These actions give the following automaton:
We may also represent the actions of each state of the automaton in bracket notation. The state $a$ acts as the transposition (01), which we commonly refer to as $\tau$. The state $b$ will act differently on 0 and 1, but it does not change the number in either case. When it acts on a 0, it returns the 0 and goes to $a$, and when it acts on a 1, it returns the 1 and goes back to itself. Therefore $b = (a, b)$.

3.2. The Iterated Monodromy Group of $p_1(z) = z^3 + 3z$.

A more interesting example comes from the polynomial $p_1(z) = z^3 + 3z$. Carrying out the same procedure explained earlier, we find $C = \{i, -i\}$ and $P = \{2i, -2i\}$. We may then create the following spider with $\gamma_{2i} = \{z \in \mathbb{C} \mid z = 2i - t, t \in \mathbb{R}^+\}$ and $\gamma_{-2i} = \{z \in \mathbb{C} \mid z = t - 2i, t \in \mathbb{R}^+\}$.

We may note it is a $p_1$-invariant spider, with $p_1(\gamma_{2i})$ and $p_1(\gamma_{-2i})$ also depicted. We also give the critical portrait, with $X_{(i)}$ and $X_{(-i)}$ depicted.
We assign the post critical points $2i$ and $-2i$ the states $a$ and $b$, respectively, and we the find the actions to be: $a\cdot 0 = 1 \cdot id, a \cdot 1 = 0 \cdot id, a \cdot 2 = 2 \cdot b$ and $b \cdot 0 = 0 \cdot a, b \cdot 1 = 2 \cdot id, b \cdot 2 = 1 \cdot id$.

We finally have our final automaton, with its Moore diagram depicted here:

![Moore diagram](image)

We may then convert the automaton into a group with the previously introduced bracket notation. This gives group elements $a = \alpha(1, 1, b)$ and $b = \beta(a, 1, 1)$, where $\alpha = (01)$ and $\beta = (12)$.

3.3. The Iterated Monodromy Group of $p_2(z) = z^3 - 3z$.

A similar example is the iterated monodromy group of $p_2(z) = z^3 - 3z$. Following the same procedure, we have $C = \{1, -1\}$ and $P = \{-2, 2\}$. We may graph $\gamma_2 = 2 + ti, \gamma_{-2} = -2 - ti$, along with $p_2(\gamma_2)$ and $p_2(\gamma_{-2})$ to create a $p$-invariant spider, figure.
The curves $X_{(1)}$ and $X_{(-1)}$ are graphed to form the critical portrait shown below.

This critical portrait leads to the following actions of the group elements $a$ and $b$. With $a$ labeling post critical point 2 and $b$ labeling $-2$, the actions of the group are: $a \cdot 0 = 1 \cdot \text{id}$, $a \cdot 1 = 0 \cdot \text{id}$, $a \cdot 2 = 2 \cdot a$ and $b \cdot 0 = 0 \cdot b$, $b \cdot 1 = 2 \cdot \text{id}$, $b \cdot 2 = 1 \cdot \text{id}$. Here we show the automaton:

In bracket notation, these group elements are represented as $a = \alpha(1,1,a)$ and $b = \beta(b,1,1)$, where $\alpha$ and $\beta$ are cycles $\alpha = (01)$ and $\beta = (12)$.

3.4. The Iterated Monodromy Group of $p_3(z) = z^2 + \frac{3}{2}z$.

For a final example, we use the post-critical polynomial $p_3(z) = z^3 + \frac{3}{2}z$. For this polynomial we have $C = \{\frac{i}{\sqrt{2}}, \frac{-i}{\sqrt{2}}\}$ and $P = \{p_3(\frac{i}{\sqrt{2}}), p_3(\frac{-i}{\sqrt{2}})\}$. We may note having $p_3$ act on either
of the critical points simply returns that point, that is, \( p_3(i \sqrt{2}) = i \sqrt{2} \) and \( p_3(-i \sqrt{2}) = -i \sqrt{2} \).

As described earlier, we chose the curves, \( \gamma(i \sqrt{2}) = \{ z \in \mathbb{C} \mid -t + i \sqrt{2} : t \geq 0 \} \) and \( \gamma(-i \sqrt{2}) = \{ z \in \mathbb{C} \mid t - i \sqrt{2} : t \geq 0 \} \) to construct the \( f \)-invariant spider \( p_3(\gamma(i \sqrt{2})) \) and \( p_3(\gamma(-i \sqrt{2})) \).

Again, we wish to create a critical portrait for the polynomial with the set of curves \( X_z = \{ p_3^{-1}(\gamma(P_3(z))) \mid z \in C \} \). Therefore our critical portrait contains two curves \( X(i \sqrt{2}) \) and \( X(-i \sqrt{2}) \), and below is the critical portrait we constructed.

This critical portrait is different than those other polynomials because its critical points are the same as its post-critical points. This causes both post-critical points lie on the curves of the critical portrait.

State \( a \) corresponds to the post critical point \( i \sqrt{2} \) and state \( b \) corresponds to the post critical point \( -i \sqrt{2} \). The group actions are for \( a \) are \( a \cdot 0 = 1 \cdot a, a \cdot 1 = 0 \cdot id, a \cdot 2 = 2 \cdot id \), and the actions for \( b \) are \( b \cdot 0 = 0 \cdot id, b \cdot 1 = 2 \cdot b, b \cdot 2 = 1 \cdot id \). The following automaton represents the group of automorphisms from this polynomial:
Note $\alpha = (01)$ and $\beta = (12)$. Thus, writing $a$ and $b$ in bracket notation gives $a = \alpha(a, 1, 1)$ and $b = \beta(1, b, 1)$.

3.5. Isomorphism with the Infinite Dihedral Group.

**Proposition 3.1.** The iterated monodromy groups of $p, p_1, p_2$, and $p_3$ have polynomial growth.

For the proof, we shall show the iterated monodromy group of $z^3 - 3z$ is isomorphic to $D_\infty$, which is a group known to have polynomial growth. The other groups proofs are similar.

**Proof.** First, note that both $\alpha$ and $\beta$ have order two, as they are simple transpositions of two letters of our alphabet. Next, we show both $a$ and $b$ are also of order 2. Taking advantage of the bracket notation, we see $a^2 = \alpha(1, 1, b)\alpha(1, 1, b) = (1, 1, b^2)$.

However, we can also show this explicitly through acting on strings of the alphabet, considering $\alpha(1, 1, b)\alpha(1, 1, b)(x_1 x_2 x_3 \ldots x_n)$ for some ternary string $x_1 x_2 \ldots x_n$. If $x_1$ is either 0 or 1, then, $(1, 1, b)$ simply acts as the identity, and since $\alpha$ acts on $x_1$ twice, it also does nothing, and, we simply find

$$\alpha(1, 1, b)\alpha(1, 1, b)(x_1 x_2 x_3 \ldots x_n) = \alpha(1, 1, b)(x_1 x_2 x_3 \ldots x_n) = (x_1 x_2 x_3 \ldots x_n).$$

On the other hand, if $x_1 = 2$, then $(1, 1, b)$ acts as the identity on $x_1$ and as $b$ on $x_2 x_3 \ldots x_n$, but $\alpha$ acts as the identity on $x_1$, as it does not permute 2. Thus,

$$\alpha(1, 1, b)\alpha(1, 1, b)(2x_2 x_3 \ldots x_n) = \alpha(1, 1, b)2b(x_2 x_3 \ldots x_n) = 2b^2(x_2 x_3 \ldots x_n).$$

Therefore, we again find $a^2 = (1, 1, b^2)$.

Using a similar process, we find $b^2 = \beta(a, 1, 1)\beta(a, 1, 1) = (a^2, 1, 1)$. Applying this inductively, we may note neither $a^2$ nor $b^2$ will ever contain an active state in any of their terms, and they will thus never act non-trivially on any string. Thus, they are both the identity, giving $a$ and $b$ each order 2.

Next, we will show the group element $ab$ and its inverse $ba$ are each of infinite order. To show this, we will assume the contrary, they are of finite order.

For this, note, $ab = \alpha(1, 1, b)\beta(a, 1, 1)$. Again taking advantage of bracket notation, this gives $ab = \alpha\beta(1, b, 1)(a, 1, 1) = \alpha\beta(a, b, 1)$. Similarly, $ba = \beta\alpha(1, a, b)$.

Note $\alpha\beta = (012)$ and $\beta\alpha = (210)$. Thus, both of these are of order 3, as they are cycles of three elements. Since $\alpha\beta$ is the only part of $ab$ not fixing the top branch of the tree, we may then note the order of $ab$ must also be a multiple of 3, else the top branch will have changed, and that multiple of $ab$ is not the identity.
Then $|ab| = 3n$ for some $n \in \mathbb{N}$. Then $(ab)^3 = ((ab)^3)^n = 1$. Note, though, $(ab)^3 = \alpha\beta(a, b, 1)\alpha\beta(a, b, 1)\alpha\beta(a, b, 1) = (ba, ab, a)$. Thus, $(ba, ab, a)^n = 1 = (1, 1, 1)$. However, $(ba, ab, a)^n = ((ba)^n, (ab)^n, a^n)$, and so $(ab)^n = 1$. This contradicts the finding that $|ab| = 3n$, as then $(ab)^n = 1$, which requires $|ab| \leq n$. Thus, $ab$ is of infinite order. A similar argument shows $ba$ has infinite order.

With both generators having order two and their products having infinite order, we know that the iterated monodromy group of $p_1(z) = z^3 - 3z$ is isomorphic to the infinite dihedral group, which is known to have polynomial growth.

A similar argument shows the iterated monodromy groups of $p, p_2$, and $p_3$ are also of polynomial growth.

\[\square\]

3.6. **Bux-Pérez Method.** Many of the techniques we use come from a paper by Bux and Pérez[2]. Most important of these is the use of weights to prove sub-exponential growth.

3.6.1. **Weights and Length Functions.**

For showing a group $G$ has sub-exponential growth, we want a length function, a function $\ell : G \to \mathbb{R}_0^+$ giving each of the elements of $G$ some non-negative weight, with $\ell(id) = 0$, $\ell(g) = \ell(g^{-1})$ for each $g \in G$, and $\ell(g_1) + \ell(g_2) \leq \ell(g_1g_2)$ for all $g_1, g_2 \in G$.

However, since we are defining a group $G$ in terms of its generating set $\Sigma$, it is difficult to find such a length function. To find one, we will consider a map $\tilde{\ell} : \Sigma \to \mathbb{R}_0^+$ assigning a strictly positive weight to each non-identity generator. Then $\tilde{\ell}$ extends to a length function $\ell$ on the set $\Sigma^*$ of all words in the alphabet $\Sigma \cup \Sigma^{-1}$, with $\tilde{\ell}(x_1^{\epsilon_1}x_2^{\epsilon_2}\cdots x_n^{\epsilon_n}) = \sum_{i=1}^n \tilde{\ell}(x_i)$ for any generic element $x_1^{\epsilon_1}x_2^{\epsilon_2}\cdots x_n^{\epsilon_n} \in \Sigma^*$, where $\epsilon_i \in \{0, 1\}$.

Then this induces a length function $\ell$ on $G$, where

$$\ell(g) = \min\{\ell(w) \mid w \text{ is a word representing } g\}$$

for any $g \in G$.

Groups with only a single active state will have only a single active generator $\tau$. Among these, some have a reduced form in which the non-$\tau$ generators generate a finite set. We will write these groups in an alternating form, $\tau^{\epsilon_0}x_1\tau x_2\cdots \tau x_n\tau^{\epsilon_2}$ where each $x_i$ is some element of the set generated by the non-$\tau$ generators, and $\epsilon_0, \epsilon_1 \in \{0, 1\}$. Each minimum length word may be written in this form.

**Definition 3.2.** For a group in $\tau$-alternating form, we say an $x_i$ is non-reducing if $\ell(\tau) + \ell(x_i) = \ell(\phi_0) + \ell(\phi_1)$. We say an $x_i$ is reducing if $\ell(\tau) + \ell(x_i) > \ell(\phi_0) + \ell(\phi_1)$. A length function is said to be admissible if every $x_i$ is either reducing or non-reducing.

We say a word is $\epsilon$-bad if it contains at most $\epsilon n$ non-reducing $x_i$. A word is $\epsilon$-good if it is not $\epsilon$-bad.
The last key piece is this proposition proved by Bux and Pérez:

**Proposition 3.3.** (Bux-Pérez) [2]

Let $H$ be a finite index subgroup of the finitely generate group $G$, and let $\ell$ be a length function on $G$ as above.

Then suppose there exist numbers $\eta \in [0, 1)$, $p \in (0, 1]$, $K \geq 0$, and an injective homomorphism

$$
\phi : H \to \left\{ \underbrace{G \times G \times \cdots \times G}_{\text{n factors}} \right\}
$$

$$
\phi(h) = (\phi_1(h), \ldots, \phi_n(h))
$$

such that for each $r \in \mathbb{N}$, the proportion of all elements in \( \{ h \in H | \ell(h) \leq r \} \) satisfying

$$
\sum_{i=1}^{n} \ell(\phi_i(h)) \leq \eta r + K
$$

is at least $p$.

Then $G$ has sub-exponential growth.

This theorem is convenient because it allows us to use properties of length reduction of word to show a group has sub-exponential growth without considering the actual elements in balls of increasing weights. Do note, however, that there is a significant difference between finding the proportion of words with the desired reduction and the proportion of elements of the group with the desired reduction.

4. **Intermediate Growth for Iterated Monodromy Groups of Quadratic Polynomials**

Consider the polynomial $z^2 + c$ where $c$ is a specific constant and $c \approx -0.228155 + 1.11514i$ where $z^2 + c$ is a root of $z^8 + 4z^7 + 6z^6 + 6z^5 + 4z^4$. Then $C = \{0\}$ and $P = \{-0.228155 + 1.11514i, -1.41964 + 0.606291i, 1.41964 - 0.606291i\}$. Using the same process as shown in the previous examples, this polynomial can be represented by the following automaton:
\[ A = \langle \tau, \alpha, \beta \rangle \]
\[ \tau = (01) \]
\[ \alpha = (1, \tau) \]
\[ \beta = (\beta, \alpha) \]

We first observe that since \( \alpha^2 = 1 \), that \( \beta^2 = (\beta^2, 1) \). Thus each of our generators has order 2. It follows now that \( \tau \alpha \tau \alpha = (\tau, \tau) \), and thus \( (\tau \alpha)^4 = 1 \). We can also see that since \( \alpha \beta = (\beta, \tau \alpha) \), we have that \( (\alpha \beta)^4 = 1 \). We also have that \( \tau \beta \tau \beta = (\alpha \beta, \beta \alpha) \), and thus \( (\tau \beta)^8 = 1 \). Thus, any subgroup created by two of the generators in \( A \) forms a quotient of one of the following dihedral groups:

\[ D_4(\tau, \alpha) := \langle \tau, \alpha \mid \tau^2 = \alpha^2 = (\tau \alpha)^4 = 1 \rangle \]
\[ D_8(\tau, \beta) := \langle \tau, \beta \mid \tau^2 = \beta^2 = (\tau \beta)^8 = 1 \rangle \]
\[ D_4(\alpha, \beta) := \langle \alpha, \beta \mid \alpha^2 = \beta^2 = (\alpha \beta)^4 = 1 \rangle \]

To represent any word \( w \) in \( A \), we can write \( w = (\tau)x_1 \tau x_2 \cdots \tau x_n(\tau) \), where \( x_i \in D_4(\alpha, \beta) \). In order to write any word \( w \) as an alternating word of \( \tau \)-letters and other generators, we can extend our generating set by making each of the elements in \( D_4(\alpha, \beta) \) a new generator. If we do this, we should let the weight of each of these new generators just be the length according to the original generating set. This lets us not worry about having to find a minimal length representation of our word. We can then list out each of the unique elements that could go between \( \tau \)-letters:

<table>
<thead>
<tr>
<th>name</th>
<th>element</th>
<th>pair</th>
<th>name</th>
<th>element</th>
<th>pair</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \alpha_1 )</td>
<td>( \alpha )</td>
<td>( (1, \tau) )</td>
<td>( \beta_1 )</td>
<td>( \beta )</td>
<td>( (\beta, \alpha) )</td>
</tr>
<tr>
<td>( \alpha_2 )</td>
<td>( \alpha \beta )</td>
<td>( (\beta, \tau \alpha) )</td>
<td>( \beta_2 )</td>
<td>( \beta \alpha )</td>
<td>( (\beta, \alpha \tau) )</td>
</tr>
<tr>
<td>( \alpha_3 )</td>
<td>( \alpha \beta \alpha )</td>
<td>( (\beta, \tau \alpha \tau) )</td>
<td>( \beta_3 )</td>
<td>( \beta \alpha \beta )</td>
<td>( (\beta, \alpha \tau \alpha) )</td>
</tr>
<tr>
<td>( \alpha_4 )</td>
<td>( \alpha \beta \alpha \beta )</td>
<td>( (1, \tau \alpha \tau) )</td>
<td>( \beta_4 )</td>
<td>( \beta \alpha \beta \alpha )</td>
<td>( (1, \alpha \tau \alpha \tau) )</td>
</tr>
</tbody>
</table>

With this extended generating set in hand, we can set up a new definition:

**Definition 4.1.** A word \( (\tau)x_1 \tau x_2 \cdots \tau x_n(\tau) \) is called a **reduced word** if each \( x_i \) is equal to a non-\( \tau \) letter in the extended generating set. A generator is then said to **occur** or be **contained** in \( w \) if it appears as a subword of \( w \). A word is also said to be **reducible** if it is not a reduced word.

Our goal now will be to apply Proposition 3.3 to prove subexponential growth. Our first step then should be to choose weights for our generators. It is important to recognize that we need to find an appropriate weight system that will minimize the amount of words that get no reduction when we split them (we should never increase the length of the word). To do this, we should try and set up some parameters for our weights so they minimize the amount of words that do not get any reduction when split into pair notation. We can do this by looking at some examples:
From $\tau \beta \tau = (\alpha \beta, \beta \alpha)$, we need to have $\ell(\tau) \geq \ell(\alpha)$. This follows from the fact that the length of $\tau \beta \tau$ is $2\ell(\tau) + 2\ell(\beta)$. The sum of the lengths of the words in the left and right coordinates of the pair notation is then $2\ell(\alpha) + 2\ell(\beta)$. We want to ensure that in the worst case scenario, we never increase the length of a word when we split it up. So as a minimal restriction, we need to have $2\ell(\tau) + 2\ell(\beta) \geq 2\ell(\alpha) + 2\ell(\beta)$. After cancellation, we then see that we at least need to satisfy $\ell(\tau) \geq \ell(\alpha)$.

In addition, $\tau \alpha \beta \alpha \tau = (\alpha \tau \beta, \beta \alpha \tau)$, which forces us to have $\ell(\alpha) \geq \ell(\alpha)$, and thus $\ell(\tau) = \ell(\alpha)$ from the first inequality. Lastly, if we look at $\tau \beta \alpha \beta \tau = (\alpha \beta \alpha, \beta \alpha \tau)$, we have $\ell(\beta) \geq \ell(\alpha)$. We now propose the weight system:

$$\ell(\tau) = 3, \ell(\alpha) = 3, \ell(\beta) = 4$$

It will not necessarily be the case that we can get all of our words to reduce in length when we split them. To prepare us for this case, we should try to at least have a global bound on the number of words of arbitrary length that get no reduction. Otherwise, it will be difficult to control the proportion of words that get less than a certain amount of reduction, a condition required to prove subexponential growth by Proposition ??]. The following definitions will set our argument up so that we can find such a global bound.

Let $w$ be a reduced word that contains an even number of $\tau$-letters. When we split $w$ into its pair notation, we will be looking for length reduction in two fundamental ways; we either create words in the pair notation that have a smaller length than $w$, or we create words in the pair notation that are reducible.

**Definition 4.2.** The first-line production of $w$ to be the product of the following algorithm:

1. Take a reduced word $w = (\tau)x_1\tau \cdots \tau x_n(\tau)$ that has an even occurrence of $\tau$-letters and expand each $x_i$ into its pair notation, denoted by $(x_{i_L}, x_{i_R})$. If $w$ represents an element in $D_4(\alpha, \beta)$, skip to (3), otherwise go to (2).

2. Take the leftmost string of the form $\tau(x_{i_L}, x_{i_R})$ inside $w$ and use the property $\tau(x_{i_L}, x_{i_R}) = (x_{i_R}, x_{i_L}) \tau$ to re-write $\tau(x_{i_L}, x_{i_R})$ as $(x_{i_R}, x_{i_L}) \tau$. Since $w$ has an even occurrence of $\tau$-letters, every time we use this re-writing rule we get the cancellation of 2 $\tau$-letters. This can be seen as follows for a string inside a word $w$:

$$\tau x_i \tau x_{i+1} = \tau(x_{i_L}, x_{i_R})\tau(x_{i+1_L}, x_{i+1_R}) = (x_{i_R}, x_{i_L}) \tau \tau(x_{i+1_L}, x_{i+1_R}) = (x_{i_R}, x_{i_L})(x_{i+1_L}, x_{i+1_R}).$$

We can then see that we can perform (2) multiple times until there are no remaining $\tau$-letters. Assuming we have done so, we can then proceed to (3).
Now that we have a word that can be expressed as a product of elements each of which is represented in the pair notation, we can multiply the elements in the left coordinate together and multiply elements in the right coordinate together. We should not perform any potential cancellation or reduction that could happen after we multiply elements together. We then call this final product the first-line production of $w$, which we will denote by $FL_P(w)$. If $FL_P(w) = (w_L, w_R)$, then we denote $w_L$ and $w_R$ by the left and right coordinates of $FL_P(w)$ respectively.

As a remark, it will be necessary to find a subgroup of finite index in $A$ to satisfy the conditions of Proposition 3.3. The simplest choice is to consider the stabilizer of the $n$th level of the tree, denoted by $A_n$. A word representing an element in $A_n$ must contain an even number of $\tau$-letters or else it acts directly on the first level of the tree (assuming $n \geq 1$). Thus it suffices to restrict our attention to reduced words that contain an even occurrence of $\tau$-letters as we did above.

**Definition 4.3.** An element $x \in D_4(\alpha, \beta)$ is good by nature if the following condition holds: $\ell(\phi_0(x)) + \ell(\phi_1(x)) < \ell(\tau) + \ell(x)$. This definition allows us to identify the simplest cases of reduction we could have inside a word $w$, as just having the occurrence of a good by nature element guarantees some type of reduction after we split it. This follows from the fact that since a reduced word can be written as $(\tau)x_1\tau \cdots \tau x_n(\tau)$, except for a potential case at the beginning or end of a word, we can associate to each $x_i$ a $\tau$-letter. Then, since $\tau$ cannot be represented in pair notation, when we split the reduced word, we immediately lose the weight of one $\tau$-letter for each $x_i$. The exception mentioned above is ultimately not problematic, as that case can only occur in at most one place in any given word.

We can now look at each of our non-$\tau$ generators then to see if they are good by nature:

<table>
<thead>
<tr>
<th>$x$</th>
<th>$\ell(\tau) + \ell(x)$</th>
<th>$\ell(\phi_L(x)) + \ell(\phi_R(x))$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\alpha_1$</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>$\alpha_2$</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>$\alpha_3$</td>
<td>13</td>
<td>13</td>
</tr>
<tr>
<td>$\alpha_4$</td>
<td>17</td>
<td>12</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>$x$</th>
<th>$\ell(\tau) + \ell(x)$</th>
<th>$\ell(\phi_L(x)) + \ell(\phi_R(x))$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\beta_1$</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>$\beta_2$</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>$\beta_3$</td>
<td>14</td>
<td>13</td>
</tr>
<tr>
<td>$\beta_4$</td>
<td>17</td>
<td>12</td>
</tr>
</tbody>
</table>

Our good by nature elements are thus: $\alpha_1$, $\alpha_4$, $\beta_3$, and $\beta_4$.

**Definition 4.4.** A primitive set $S$ of good blocks is a finite set of reduced words (the good blocks) that have an even occurrence of $\tau$-letters such that each $w \in S$ satisfies one of the following:
(i) For $FL_P(w) = (w_L, w_R)$, at least one of $w_L$ or $w_R$ is reducible.

(ii) Both words in $FL_P(w)$ are reduced and represent elements in $A_1$, and $FL_P(w_L)$ or $FL_P(w_R)$ is reducible in at least one of $w_{LL}$, $w_{LR}$, $w_{RL}$, or $w_{RR}$.

(iii) A good by nature element occurs between two $\tau$-letters in one of the reduced coordinates of $FL_P(w)$, and that coordinate is also in $A_1$.

(iv) For $FL_P(w) = (w_L, w_R)$, either $FL_P(w_L)$ or $FL_P(w_R)$ has a coordinate in $A_1$ that has an occurrence of a good by nature element in between two $\tau$ letters.

(v) The element represented by $w$ is good by nature.

Definition 4.5. An $S$-bad block is a reduced word $(\tau)x_1\tau \cdots \tau x_n(\tau)$ containing no occurrence of any $w \in S$.

Our goal will now be the following:

(*) Find an appropriate primitive set $S$ of good blocks such that the number of $S$-bad blocks containing $i$ non-$\tau$ letters is globally bounded by some $M$, for any $i$.

Proposition 4.6. There is a primitive set $S$ of good blocks for the subgroup $A_3$ that satisfies (*).

Proof. We first propose the following primitive set $S$ of good blocks:

$$S = \left( \bigcup_{i=1}^{8} P_i \right) \cup \{\alpha_1\} \cup \{\alpha_4\} \cup \{\beta_3\} \cup \{\beta_4\} \cup \{\alpha_3\},$$

where each $P_i$ is defined below.

It is easy to see that $\alpha_1$, $\alpha_4$, $\beta_3$, and $\beta_4$ condition (v) of Definition (4.4) to be in a primitive set of good blocks. Since $FL_P(\alpha_3) = (\beta, \tau \alpha \tau)$, it follows that $\tau \alpha \tau$ contains an occurrence of a good by nature element isolated between two $\tau$-letters, so $\alpha_3$ satisfies condition (iii) of Definition (4.4). We will now define each $P_i$ and verify that each set consists of blocks that are in $S$.

First, observe that if we let $\Box$ be an arbitrary element in the set $\{\beta_1, \beta_2, \alpha_2\}$ and $FL_P(\Box) = (\Box_L, \Box_R)$, then $\Box_L = \beta$. It follows then that for $w = \tau \Box \tau$, we have $w_R = \beta$.

From here define the following sets that contain blocks in $S$. 

17
$P_1$: For a block $b \in P_1$, $b$ has the form $\tau \alpha \beta \alpha \beta \alpha \beta$ and creates the string $\beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Thus, every word in $P_1$ meets condition (i) of Definition (4.4) as $\beta \alpha \beta \alpha \beta$ can be reduced to $\alpha \beta \alpha$.

$P_2$: For a block $b \in P_2$, $b$ has the form $\square \tau \alpha \beta \alpha \beta \alpha \beta$ and creates the string $\square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Since $\square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ can only contain $\alpha$ or $\tau$-letters, it follows that if $\square \tau \alpha \beta \alpha \beta \alpha \beta$ ends in $\tau$, we meet condition $(i)$. If $\square \tau \alpha \beta \alpha \beta \alpha \beta$ ends in $\alpha$, then we meet condition $(i)$. Thus, every word in $P_2$ meets either condition (i) or (iii).

$P_3$: For a block $b \in P_3$, $b$ has the form $\beta_2 \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ and creates $\alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ respectively in $b_R$. Thus, in either case, every word in $P_3$ meets condition (iii).

$P_4$: For a block $b \in P_4$, $b$ has the form $\tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ and creates $\beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Thus, every word in $P_4$ meets condition (i).

$P_5$: For a block $b \in P_5$, $b$ has the form $\beta_2 \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ and creates $\alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Thus, in either case, every word in $P_5$ meets condition (iii).

$P_6$: For a block $b \in P_6$, $b$ has the form $\tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ and creates $\beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. It follows then that $FL_P(b_R)$ creates $\alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Thus, every word in $P_6$ meets condition (iv).

$P_7$: For a block $b \in P_7$, $b$ has the form $\alpha_2 \tau \square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ and creates $\tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ in $b_R$. Since $\square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ can only contain $\alpha$ or $\tau$-letters, it follows that if $\square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ begins with $\alpha$, then we satisfy condition (i). If $\square \tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ begins with $\tau$, then we satisfy condition (iii). Thus, every word in $P_7$ satisfies condition (i) or (iii).

$P_8$: For a block $b \in P_8$, $b$ has the form $\alpha_2 \tau \square \tau \alpha \beta \alpha \beta$ and creates $\tau \alpha_3 \tau$ in $b_R$. It follows then that $\square \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$ contains $\tau \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta \alpha \beta$. Thus, every word in $P_8$ meets condition (iv).

Now that we have our primitive set $S$, we can prove the proposition. Since a reduced word $w$ is of the form $\cdots \tau x_{i-1} \tau x_i \tau x_{i+1} \cdots$, if $w$ is an $S$-bad block, then it cannot contain an occurrence of $\alpha_1, \alpha_3, \alpha_4, \beta_1$, or $\beta_3$. Thus, every $S$-bad block is of the form $\cdots \tau \tau \tau \cdots$

We can then show that the number of ways to arrange the elements from $\{\alpha_2, \beta_1, \beta_2\}$ in an $S$-bad block is finite, and hence we have a global bound.

Consider an arbitrary $S$-bad word of the form: $\cdots \tau \tau \tau \tau \tau \cdots$. It is sufficient to only show that there are a finite number of choices for $\tau, \tau, \tau, \tau, \tau, \cdots$, since we must have the exact same restriction for $\tau, \tau, \tau, \tau, \tau, \cdots$, and thus there are only a finite number of choices for the whole word to remain an $S$-bad block. Before we do a case analysis though, we should remark that we are allowed to assume our $S$-bad block has sufficiently many non-$\tau$ letters in its reduced word to give the patterns described below, otherwise we could just
use the finite bound that contains these small words. Otherwise we can say we have a finite bound since we would have only a finite number of cases that do not meet this condition.

**Case I:** \( \square_1 = \alpha_2 \)

Given this, we cannot have \( \square_3 = \beta_2 \) or else we create a block in \( P_8 \). If \( \square_3 = \beta_1 \), then regardless of our choice for \( \square_5 \), we will create a block from \( P_7 \). Thus the only way a string \( \alpha_2 \tau \square \tau \beta_1 \) can occur is at the end of a word in order to remain an \( S \)-bad block. Essentially then, except for a small amount of variation at the beginning and end of the word, if \( \square_i = \alpha_2 \), then every other \( \square \) to the right of \( \alpha_2 \) must also be \( \alpha_2 \).

**Case II:** \( \square_1 = \beta_1 \)

Given this, if \( \square_3 = \beta_2 \), then assuming there are at least 2 non-\( \tau \) letters to the left of \( \square_1 \), this creates a block from \( P_3 \). If \( \square_3 = \beta_1 \), again assuming there is at least one non-\( \tau \) letter to the left of \( \square_1 \) and one \( \tau \)-letter to the right of \( \square_3 \), this creates a block from \( P_1 \). If \( \square_3 = \alpha_2 \), then assuming there at least three non-\( \tau \) letters to the left of \( \square_1 \), we create a word from either \( P_3 \) or \( P_4 \). Thus, the only place \( \beta_1 \) can appear is near the beginning or end of a word, otherwise we make a good block from \( S \).

**Case III:** \( \square_1 = \beta_2 \)

Given this, say \( \square_3 = \beta_1 \). If \( \square_5 = \beta_2 \), we create a block in \( P_5 \). If \( \square_5 = \alpha_2 \), then we create a block in \( P_3 \). If \( \square_5 = \beta_1 \), then assuming we have at least \( \tau \square \tau \) to the right of \( \square_5 \), we have made a block in \( P_1 \). Thus, \( \beta_2 \tau \square \tau \beta_1 \) can only appear near the beginning or end of a word. Say now that \( \square_3 = \alpha_2 \), then as a result from Case I, every other non-\( \tau \) letter to the right of \( \square_3 \) must be \( \alpha_2 \), except for some variation at the end of the word. Without considering our options for \( \square_3 = \beta_2 \), we claim that we now have enough information to prove the claim.

We discovered in Case I that if \( \alpha_2 \) occurs in an \( S \)-bad block at position \( i \) in a word \( w \) then every letter at position congruent to \( i \) modulo 4 to the right of \( i \) must also be \( \alpha_2 \). If \( \beta_2 \) occurs in a \( S \)-bad block at position \( i \) then we have 2 subcases to consider.

The first subcase is we have a string of \( \beta_2 \)-letters at positions \( i \) modulo 4 up until position \( j \), where \( \alpha_2 \) is at position \( j \). Thus every subsequent position \( j \) modulo 4 we have \( \alpha_2 \). Every long enough string of this form contains as a substring a block in \( P_6 \). Hence this subcase cannot occur in an \( S \)-bad block. The other subcase to consider is that if we \( \beta_2 \) at position \( i \), then at every subsequent position \( i \) modulo 4, we must also have \( \beta_2 \). This subcase then never creates a substring in \( P_1 \), for arbitrary \( i \).

Thus if we fix either \( \alpha_2 \) or \( \beta_2 \) at position \( i \) in a word, for sufficiently long words we can guarantee that every position \( i \) modulo 4 to the right of \( i \) must be the same letter that occurs at position \( i \) except for some variation at the end of the word.
It follows then that there is a global bound $M$ on the number of $S$-bad blocks that contain $i$ non-$\tau$ letters since after we pick the first few non-$\tau$ letters at the end and beginning of a word, the rest of the word is essentially a proper power of one of the following words:

(i) $\beta_2 \tau \beta_2 \tau$  
(ii) $\beta_2 \tau \alpha_2 \tau$  
(iii) $\alpha_2 \tau \alpha_2 \tau$

Let $A_3$ be the subgroup in $A$ that stabilizes the first three levels of the tree. Consider now the injective homomorphism:

$$\phi: A_3 \to A^8$$

that maps $g \in A_3$ to the ordered 8-tuple $(\phi_{LLL}(g), \phi_{LLR}(g), \cdots, \phi_{RRR}(g))$.

We will now want to count the number of alternating words that represent elements in $A_3$ that contain a certain proportion of good letters. First, fix some small $\epsilon > 0$.

**Definition 4.7.** An alternating word $w$ containing $n$ non-$\tau$ letters is called $\epsilon$-bad if at most $\epsilon n$ of its non-$\tau$ letters occur in good blocks in $S$.

**Definition 4.8.** A non-$\tau$ letter is called good by position if it belongs to a block in $S$.

We now propose the following bound on the number of $\epsilon$-bad elements in $A_3$ containing $n$ non-$\tau$ letters, which we will denote by $b_\epsilon(n)$:

$$b_\epsilon(n) \leq 2 \left( \binom{n}{\lfloor \epsilon n \rfloor} \right) 7^{\lfloor \epsilon n \rfloor} M^{1+\lfloor \epsilon n \rfloor}$$

- The 2 accounts for the choice of starting with a $\tau$-letter or not.

- The $\binom{n}{\lfloor \epsilon n \rfloor}$ accounts for the number of ways to designate positions for good by position letters.

- The $7^{\lfloor \epsilon n \rfloor}$ accounts for the maximum number of ways to place good by position letters.

- The $M^{1+\lfloor \epsilon n \rfloor}$ accounts for the maximum number of choices to place $S$-bad blocks. The $1 + \lfloor \epsilon n \rfloor$ is explained by the fact that once we place our good by position letters, we break up the word into at most $1 + \lfloor \epsilon n \rfloor$ compartments to place $S$-bad blocks.

Since $\alpha$ is the lowest weight non-$\tau$ generator, a word of length $r$ containing the most non-$\tau$ letters would alternate between $\alpha$-letters and $\tau$-letters. We thus have that any word of length $r$ contains at most $(r + 3)/6$ non-$\tau$ letters.

Denote by $B_\epsilon(r)$ the number of words in $\{g \in A_3 \mid \ell(g) \leq r\}$ that contain at most $\epsilon n$ non-$\tau$ letters.
It follows then that
\[ B_\epsilon(r) \leq \sum_{n=0}^{(r+3)/6} b_\epsilon(n) \leq \left( \frac{r+3}{3} \right)^{(r+3)/6} \left( \frac{(r+3)/6}{\lfloor \epsilon(r+3)/6 \rfloor M^{1+\lfloor \epsilon(r+3)/6 \rfloor}} \right)^7 \]

**Proposition 4.9.** \( \mathcal{A} \) has subexponential growth.

*Proof.* Assume now that \( \mathcal{A} \) has exponential growth. Then \( \mathcal{A}_3 \) has exponential growth as well [cite da bux]. Let \( \lambda > 1 \) be the growth rate of \( \mathcal{A}_3 \). By Stirling’s formula, choose \( \epsilon > 0 \) so that \( \lambda^r \) grows faster than the number of elements in \( B_\epsilon(r) \). We then observe then that for any \( w \in S \), after splitting \( w \) at most two times, we either create a reducible word or create a good by nature element between two \( \tau \) letters. Thus, after splitting \( w \) at most three times we are guaranteed to have reduction by at least some fixed amount. This is true since we either get immediate reduction in the former case, or get reduction after splitting again in the latter case. Since \( S \) is a finite set, there is a word that gets the worst reduction such that we can guarantee any other word in \( S \) reduces by at least that much. Thus there is a number \( \eta \) depending on \( \epsilon \) that satisfies Proposition 3.3. This in turn implies that \( \mathcal{A}_3 \) has subexponential growth, \( \square \).

**Proposition 4.10.** \( \mathcal{A} \) has super-polynomial growth:

*Proof.* Consider \( \mathcal{A}_1 \triangleleft \mathcal{A} \) and let \( \phi : \mathcal{A}_1 \to \mathcal{A} \times \mathcal{A} \) be the injective homomorphism used before. It follows then that \( \mathcal{A}_1 \cong \phi(\mathcal{A}_1) \). Let \( N_\tau \) be the normal closure of \( \tau \). It follows that the factor group \( \mathcal{A}/N_\tau \) has order at most \( |\langle \alpha, \beta \rangle| = 8 \) since the coset \( \tau N_\tau = N_\tau \) in \( \mathcal{A}/N_\tau \). Thus \( [\mathcal{A} : N_\tau] \leq 8 \).

Since \( \alpha \) and \( \tau \alpha \tau \) are in \( \mathcal{A}_1 \), it follows that \( \langle \phi(\alpha), \phi(\tau \alpha \tau) \rangle = \langle (1, \tau), (\tau, 1) \rangle \leq \phi(\mathcal{A}_1) \). It is easy to see that \( N_\tau \times 1 \subset \phi(\mathcal{A}_1) \) since given any \( x \in \mathcal{A}_1 \) such that \( \phi(x) = (x_0, x_1) \), we have that \( \phi(x \tau \alpha \tau x^{-1}) = (x_0 \tau x_0^{-1}, 1) \). Thus, by definition, the left coordinate of \( \phi(x) \) is in \( N_\tau \). Similarly, \( 1 \times N_\tau \subset \phi(\mathcal{A}_1) \), and thus \( N_\tau \times N_\tau \subset \phi(\mathcal{A}_1) \).

Then \( [\mathcal{A} \times \mathcal{A} : \phi(\mathcal{A}_1)] \leq [\mathcal{A} \times \mathcal{A} : N_\tau \times N_\tau] = [\mathcal{A} : N_\tau]^2 \leq 8^2 = 64 \). This conclusion proves that \( \mathcal{A} \) and \( \mathcal{A} \times \mathcal{A} \) are commensurable. Using a known theorem [Terpstra], if the finitely generated infinite group \( G \) is commensurable with \( G^m \) then \( G \) cannot have polynomial growth, \( \mathcal{A} \) has super-polynomial growth.

\( \square \)

Therefore, \( \mathcal{A} \), as claimed, has intermediate growth.
5. Groups not from Polynomials

Although many of the most interesting groups we studied were the iterated monodromy groups of polynomials, not all of these groups had easy to identify growth. However, slight modifications to the group could result in a group of such simpler structure. No polynomial yields the groups \( \mathbb{Z}_k \) below, but as groups of intermediate growth on a binary tree, they are still somewhat enlightening.

5.1. Groups \( \mathbb{Z}_k \) have Intermediate Growth.

For \( k \geq 3 \), we define the group \( \mathbb{Z}_k = \langle \tau, L_1, L_2, \ldots, L_{n-1}, L_n \rangle \) by

\[
L_1 = (\tau, L_2) \\
L_k = (1, L_1) \\
L_i = (1, L_{i+1}) \quad \text{for } 1 < i < n,
\]

where \( \tau \) is the transition element and the elements in parentheses are simply elements in bracket notation, mapped into the homomorphism of the direct product \( \mathbb{Z}_k \times \mathbb{Z}_k \).

These groups have been previously shown to be of intermediate growth. In particular, the group \( \mathbb{Z}_3 \) is known as the Grigorchuk overgroup. Regardless, we offer an original proof here.

First, let us show each element \( L_i \) in any \( \mathbb{Z}_k \) is order 2 for all \( 1 \leq i \leq k \). Consider \((L_i)^2\) for any \( i \). Taking advantage of the bracket notation’s term-by-term multiplication, we may note \((L_i)^2 = (1, (L_j)^2)\) for some \( 1 \leq j \leq k \). However, in a similar manner, \((L_{i+1})^2 = (1, (L_{i+2})^2)\), so applying this repeatedly, we find \((L_i)^2 = (1, (1, (1, \ldots)))\), which is the identity element.

Next, let us consider any element of the set

\[
P = \{L_{j_1}L_{j_2}\ldots L_{j_k} | j_i \text{ are unique integers from 1 to } k\}
\]

of products of all \( L_1, L_2, \ldots, L_k \) in any order. Any element \( p \in P \) will have \( p = (\tau, p') \), for some \( p' \in P \). Again, if we apply this repeatedly, we find \( p = (\tau, (\tau, (\tau, \ldots))) \) for all \( p \in P \), and all \( p \in P \) are the same element.

We may now apply this to show all \( L_i \) generating \( \mathbb{Z}_k \) are commutative. For any \( L_i, L_j \), where without loss of generality, \( i < j \), consider the elements

\[
L_iL_jL_1L_2\ldots L_{i-1}L_{i+1}\ldots L_{j-1}L_{j+1}\ldots L_{k-1}L_k
\]

and

\[
L_jL_iL_1L_2\ldots L_{i-1}L_{i+1}\ldots L_{j-1}L_{j+1}\ldots L_{k-1}L_k.
\]

Note these are both in \( P \), so they are equal. Thus, multiplying each of them by

\[
L_1L_2\ldots L_{i-1}L_{i+1}\ldots L_{j-1}L_{j+1}\ldots L_{k-1}L_k
\]

on the right, we find the two reduce to \( L_iL_j \) and \( L_jL_i \), respectively, and so \( L_iL_j = L_jL_i \), as desired.
Since the $L_i$ are commutative and of order 2, we may now choose an alternating form for elements of $\mathbb{Z}_k$. Specifically, note we may write any element $z \in \mathbb{Z}_k$ in the minimum length form

$$z = \tau^{\epsilon_0}x_1\tau x_2\tau x_3\tau \ldots x_{n-1}\tau x_n^{\epsilon_1}$$

where $\epsilon_0, \epsilon_1 \in \{0, 1\}$ and $x_i \in \langle L_1, L_2, \ldots L_k \rangle$.

To show $\mathbb{Z}_k$ has intermediate growth, we will apply Proposition 3.3 and a process of Bux and Perez to show it has sub-exponential growth and a technique given by Terpstra to show it has super-polynomial growth.

**Theorem 5.1.** The group $\mathbb{Z}_k$ has sub-exponential growth for all $k \in \mathbb{N}$, $k \geq 3$.

To prove theorem 5.1, we shall apply a process given by Bux and Perez, first bounding the number of $\epsilon$-bad elements in any ball of radius $r$, then finding a contradiction by assuming the group has exponential growth and noting this will require the group to meet the hypothesis for Proposition 2.0.1, which gives it sub-exponential growth.

**Proof.**

For our length function, we shall choose the weights, for $1 < i \leq k$:

$$\ell(\tau) = k^2$$
$$\ell(L_1) = k$$
$$\ell(L_i) = i - 1$$

Let us now show that there is only a single non-reducing element in $C = \langle L_1, L_2, \ldots L_k \rangle$, which forces any non-reducing $x_i$ to be that element. First, note since all $L_i$ commute and are of order 2, an element $c$ of $C$ is of the form $c = (L_1)^{\epsilon_1}(L_2)^{\epsilon_2} \ldots (L_k)^{\epsilon_k}$, where $\epsilon_i \in \{0, 1\}$.

Next, note $\tau$ has a length greater than the remaining generators combined. Thus, since $L_1$ is the only generator of $C$ that gives a $\tau$ when put in bracket notation, any elements of $C$ with $\epsilon_1 = 0$ will not contain a $\tau$, and they will thus reduce.

For an element $c \in C$ with $\epsilon_1 = 1$, note $L_1 = (\tau, L_2)$. Thus, the reduction in length from putting $L_1$ in bracket notation is exactly $\ell(L_1) - \ell(L_2) = n - 1$. Furthermore, each $L_i$ we include gives an increase in length of only 1 when put in bracket notation. Thus, if even a single $\epsilon_i$ is zero, the reduction from $L_1$ will be greater than the increase from all the $L_i$ combined, giving $c$ a net length reduction.

Thus, the only $c \in C$ that might not reduce is the element $L_1L_2\ldots L_k$. Indeed, as $L_1L_2\ldots L_k = (\tau, L_1L_2\ldots L_k)$, we find it has exactly the length it began with.

For a given $r \in \mathbb{N}$, using the chosen weights, there exists an integer $K_r$ such that an alternating word $w$ of length $\ell(w) \leq r$ contains at most $K_r = \lfloor k^2 + 1 \rfloor$ total $x_i$, where $k^2 + 1$ is the combined weight of a $\tau$ and the least weighted $x_i$, $L_2$. Let $b_\ell(n)$ be the number of $\epsilon$-bad alternating words that have exactly $n$ $x_i$ and represent an even element of $\mathbb{Z}_k$. Then,

$$b_\ell(n) \leq 2 \binom{n}{\lfloor \epsilon_n \rfloor} (2^k - 1)^{\lfloor \epsilon_n \rfloor},$$

where the leading 2 accounts for the choice of starting with $\tau$ or not, the binomial coefficient
counts the number of way to allocate the \( \lfloor \epsilon n \rfloor \) positions where reducing \( x_i \) may be placed, and the factor \((2^k - 1)^{\lfloor \epsilon n \rfloor}\) counts the ways we may choose which reducing \( x_i \) are placed in the allocated positions.

We can estimate the number \( B_\epsilon(n) \) of \( \epsilon - \text{bad} \) group elements of length at most \( r \) by noting:

\[
B_\epsilon(r) \leq \sum_{n=0}^{K_r} b_\epsilon(n) \leq 2K_r \left( \frac{K_r}{\epsilon K_r} \right) (2^k - 1)^{\lfloor \epsilon K_r \rfloor}.
\]

This is a direct application of the previous equation, using \( \frac{k^2+r}{2^k+1} \) as the greatest possible \( n \) for the given \( r \), then summing all the \( b_\epsilon \) for that and lower \( n \).

Now suppose \( \mathcal{Z}_k \) has exponential growth. Then the index 2 subgroup \( H_k \) of elements of \( \mathcal{Z}_k \) with an even number of \( \tau \) has exponential growth with respect to the restricted length \( \ell|_H \). Let \( \lambda > 1 \) be the growth rate of \( H_k \). Using Stirling’s formula, we can choose \( \epsilon > 0 \) small enough so that \( \lambda^r \) grows faster than \( B_\epsilon(r) \). In particular, for \( r \) big enough, at least half of the elements in \( \{ z \in H_k \mid \ell(z) \leq r \} \) are \( \epsilon \)-good (smaller \( r \)'s are covered by the constant \( K \)).

We finish the proof by observing that an \( \epsilon \)-good element has either \( n, n+1 \), or \( n-1 \) copies of \( \tau \). If it has either \( n \) or \( n+1 \) such \( \tau \), then the \( \epsilon \)-good element reduces by at least:

\[
\eta = \frac{en(k^2+k/2 - 2) + (1-\epsilon)n(k^2+k/2) + nk^2}{en(k^2+k/2) - 1) + (1-\epsilon)n(k^2+k/2) + nk^2} < 1,
\]

where the top of the fraction is the weight of the reduced element, and the bottom the pre-reduced. This is the worst case scenario, where each of the \( en \) reducing \( x_i \) are the element \( L_1L_3...L_k \), which has a weight of \( \frac{k^2+k}{2} - 1 \) but only reduces in length by 1.

If our \( \epsilon \)-good element has \( n-1 \) copies of \( \tau \), then we will have an identical \( \eta \) if we simply increase the constant \( K \) by \( \frac{k^2+k}{2} \). The worst case is attained when the only \( x_i \) of the \( \epsilon \)-good element is the element \( L_1L_2...L_n \).

We have thus verified the hypothesis for proposition 2.0.1 with \( \eta < 1, p = \frac{1}{2} \), and \( K = \frac{k^2+k}{2} \). Thus, \( \mathcal{Z}_k \) is found to have sub-exponential growth, contradicting our assumption that it has exponential growth. Therefore, \( \mathcal{Z}_k \) has sub-exponential growth.

\[\Box\]

Next, we wish to show \( \mathcal{Z}_k \) has super-polynomial growth. For this, we shall use a technique similar to that used by Terpstra. To show \( \mathcal{Z}_k \) is commensurable with its direct product, and thus of super-polynomial growth, we will demonstrate a group \( \mathcal{B} \) is of finite index of \( \mathcal{Z}_k \) and is a subgroup of \( H_k \). From there, we will conclude \( H_k \) is of finite index in \( \mathcal{Z}_k \) and its isomorphic copy is of finite index in \( \mathcal{Z}_k \times \mathcal{Z}_k \), which is sufficient to show super-polynomial growth.

**Theorem 5.2.** The group \( \mathcal{Z}_k \) has super-polynomial growth for all \( k \in \mathbb{N}, k \geq 3 \).

**Proof.**

Choose \( \mathcal{B} = \{ zLz^{-1} \mid L \in \langle L_1, \ldots, L_{k-1} \rangle; z \in \mathcal{Z}_k \} \), that is, the normal closure of \( \langle L_1, \ldots, L_{k-1} \rangle \).
Note, then, \( \mathcal{Z}_k / \mathbb{B} \) is a group generated by the images of \( L_n \) and \( \tau \), so \( [\mathcal{Z}_k : \mathbb{B}] \leq |\langle L_n, \tau \rangle| = 8 \).

Since we have an injective homomorphism \( \phi : H_k \to \phi(H_k) \), we know \( H_k \) is isomorphic to \( \phi(H_k) \). Furthermore, note for each \( L \in \langle L_1, \ldots, L_{k-1} \rangle \), we have \((1, L')\) and \((L', 1)\) in \( \phi(H_k) \), where if \( L = L_{a_1}L_{a_2} \cdots L_{a_m} \), then \( L' = L_{a_1+1}L_{a_2+1} \cdots L_{a_m+1} \).

Let \( z_0 \in \mathcal{Z}_k \). Then there exists \( z_1 \in \mathcal{Z}_k \) such that \((z_0, z_1) \in \phi(H_k)\). Thus, \((z_0, z_1)^{-1} = (z_0^{-1}, z_1^{-1}) \in \phi(H_k)\). Putting these together, we find \((z_0, z_1)(L, 1)(z_0^{-1}, z_1^{-1}) = (z_0Lz_0^{-1}, 1) \in \phi(H_k)\). Similarly, \((1, z_0Lz_0^{-1}) \in \phi(H_k)\). Note, the respective sets of all such \((z_0Lz_0^{-1}, 1)\) and \((1, z_0Lz_0^{-1})\) are exactly \( \mathbb{B} \times 1 \) and \( 1 \times \mathbb{B} \). However, if \( \mathbb{B} \times 1 \) and \( 1 \times \mathbb{B} \) are both subgroups of \( \phi(H_k) \), then their product \( \mathbb{B} \times \mathbb{B} \) is also a subgroup of \( \phi(H_k) \).

Since \( \mathbb{B} \) has finite index in \( \mathcal{Z}_k \), we know \( \mathbb{B} \times \mathbb{B} \) has finite index in \( \mathcal{Z}_k \times \mathcal{Z}_k \). Thus, since \( \mathbb{B} \times \mathbb{B} \) is a subgroup of \( \phi(H_k) \), we find \( \phi(H_k) \) must also have finite index in \( \mathcal{Z} \times \mathcal{Z} \). Therefore, \([\mathcal{Z} : H_k]\) and \([\mathcal{Z} : \phi(H_k)]\) are both finite, where \( H_k \) is isomorphic to \( \phi(H_k) \), and so \( \mathcal{Z}_k \) is commensurable with \( \mathcal{Z}_k \times \mathcal{Z}_k \). Thus, \( \mathcal{Z}_k \) has super-polynomial growth, as desired.

\[ \square \]

We have found each \( \mathcal{Z}_k \) for \( k \geq 3 \) to have both sub-exponential and super-polynomial growth. Thus, each such \( \mathcal{Z}_k \) has intermediate growth.
